

Biology is the only subject in which
multiplication is the same thing
as **division**...

The Cell Cycle: Cell Growth, Cell Division Ch. 10

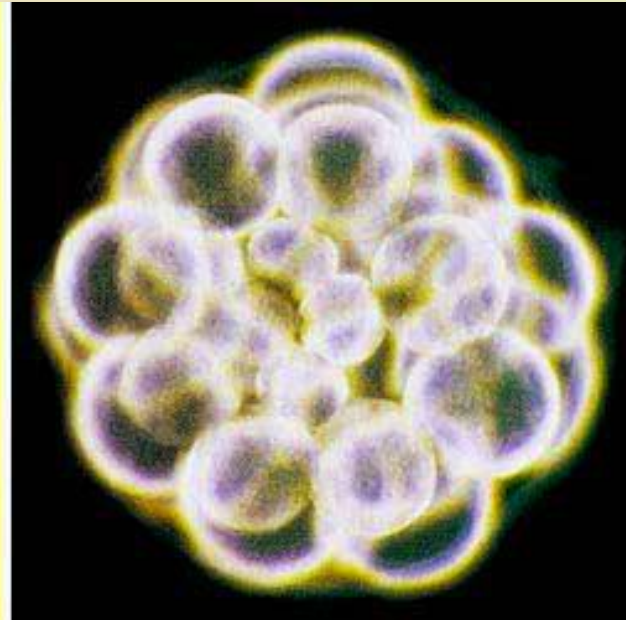

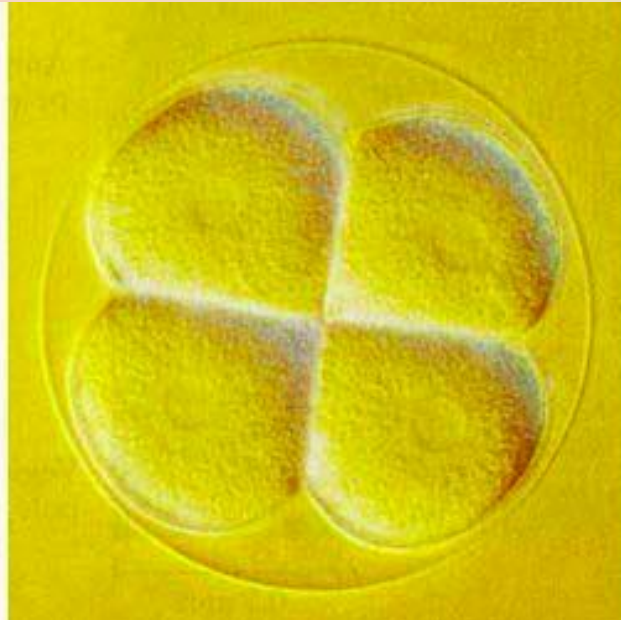

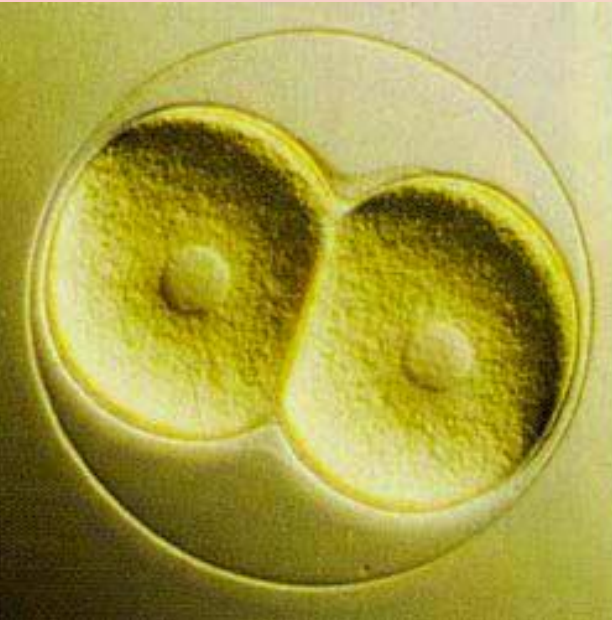

Where it all began...

You started as a cell smaller than
a period at the end of a sentence...

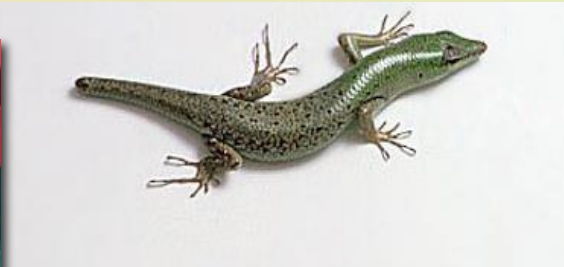

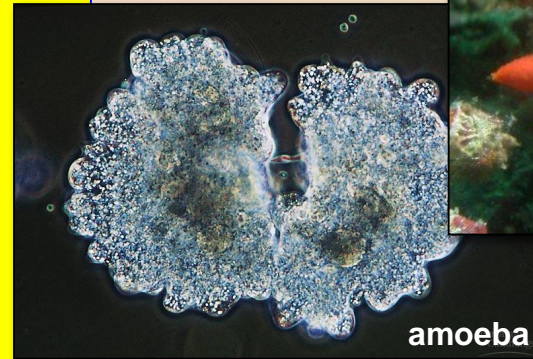

Getting from there to here...

- Going from egg to baby....
the original fertilized egg (zygote) has to divide...
and divide...
and divide...
and divide...

Why do cells divide?

- For reproduction
 - asexual reproduction
 - one-celled organisms
- For growth
 - from fertilized egg to multi-celled organism
- For repair & renewal
 - replace cells that die from normal wear & tear or from injury

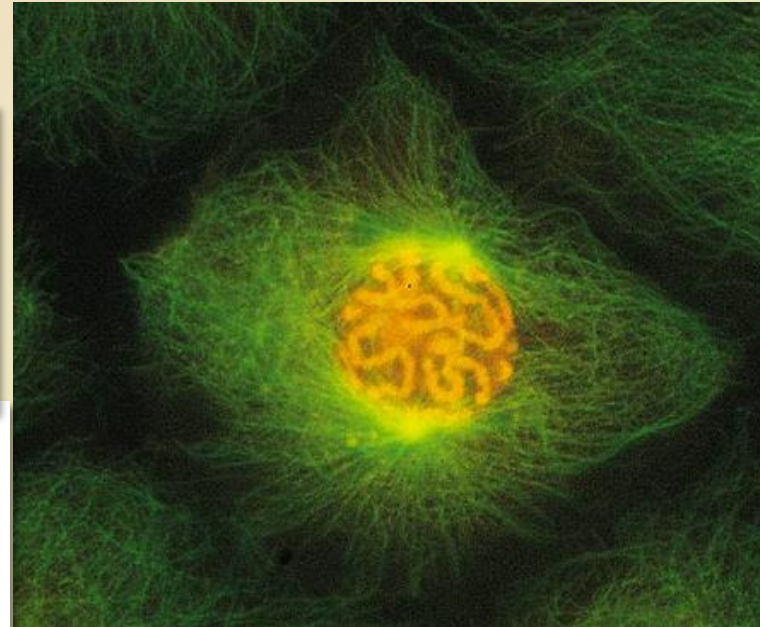

Getting the right stuff

- What is passed on to daughter cells?
 - exact copy of genetic material = DNA
 - organelles, cytoplasm, cell membrane, enzymes

chromosomes (stained orange)
in kangaroo rat epithelial cell
→notice cytoskeleton fibers

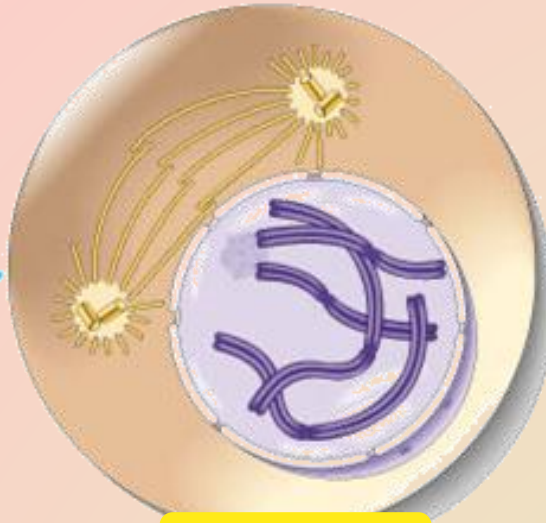

Overview of mitosis

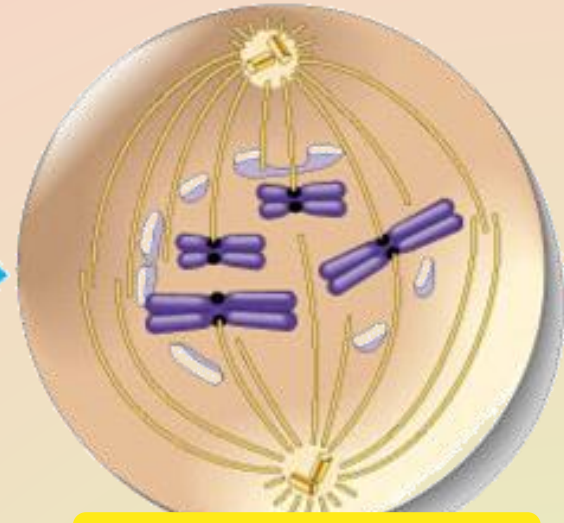

I.P.M.A.T.

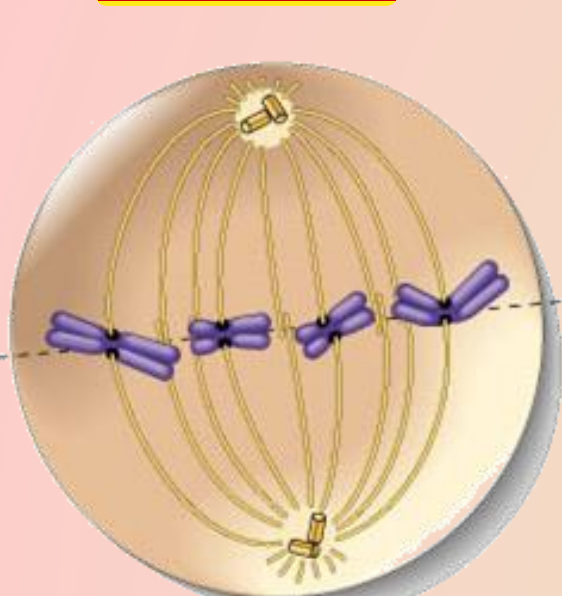

interphase

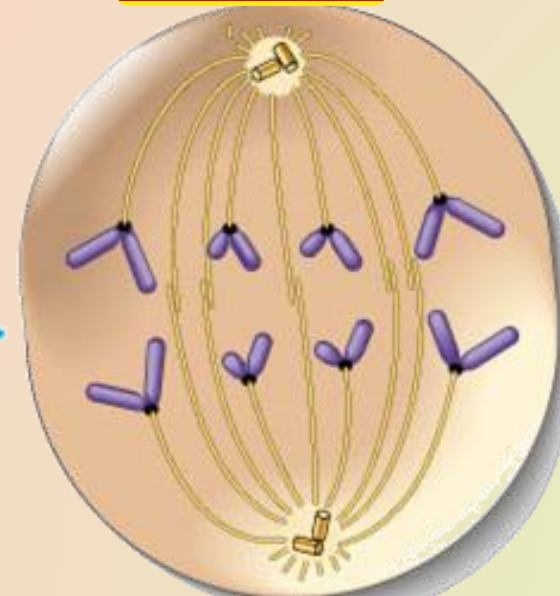

prophase

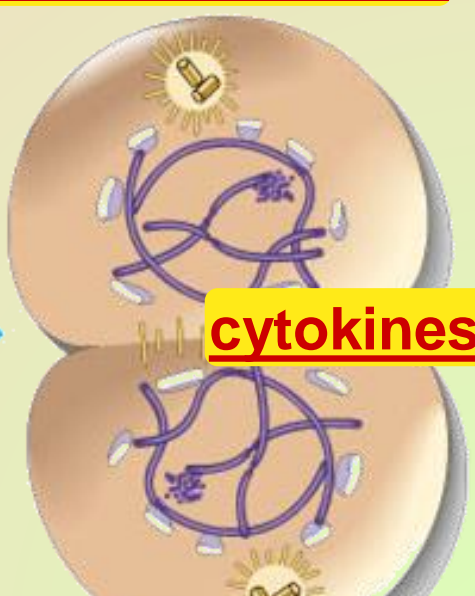

(pro-metaphase)

metaphase

anaphase

cytokinesis

telophase

Cell cycle

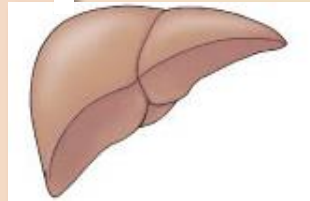

- Cell has a “life cycle”

cell is formed from
a mitotic division

cell grows & matures
to divide again

G_1, S, G_2, M

epithelial cells,
blood cells,
stem cells

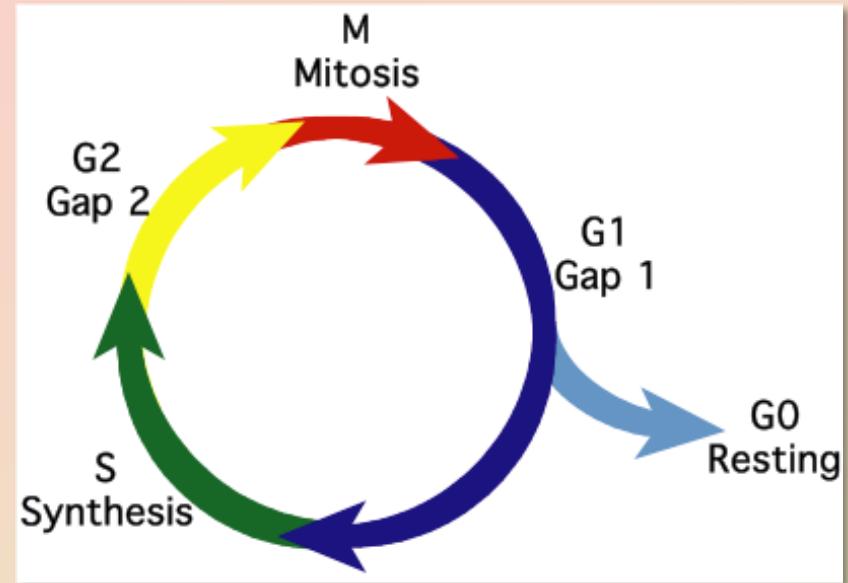

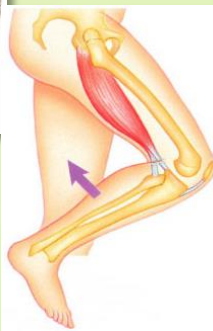

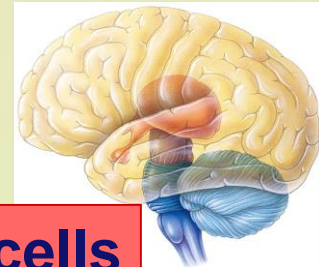

liver cells

cell grows & matures
to never divide again

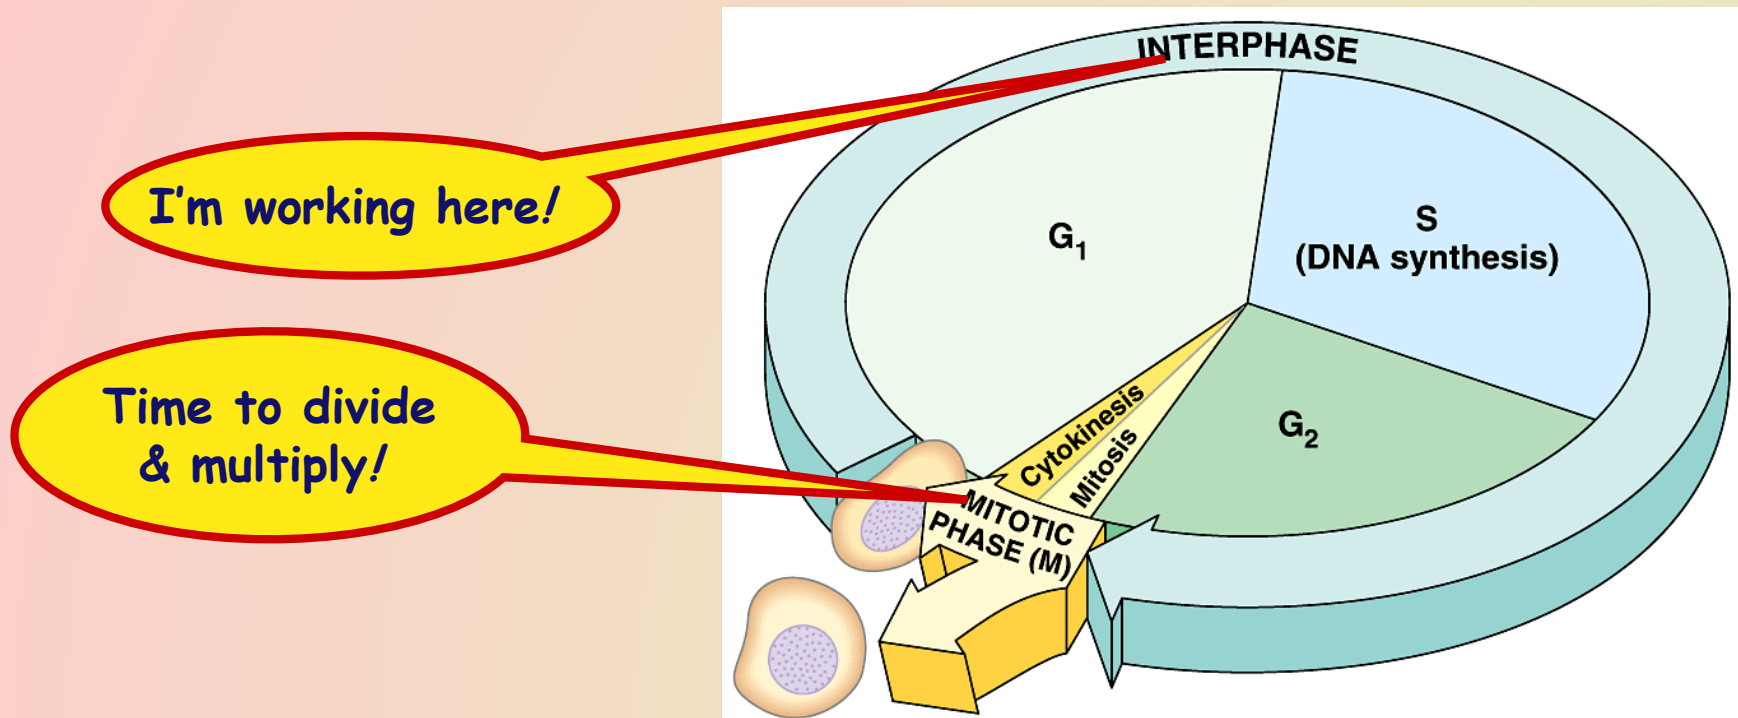

$G_1 \rightarrow G_0$

brain / nerve cells
muscle cells

Interphase

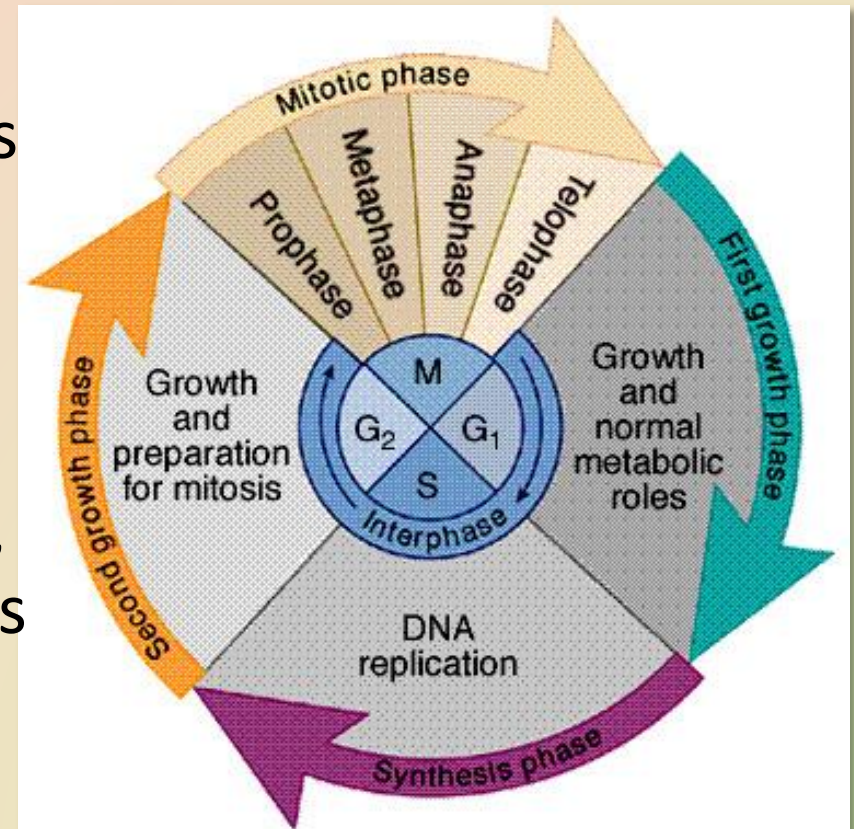

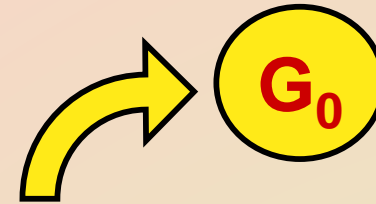

- Most of a cell's life cycle (~95%)
 - cell doing its “everyday job”
 - synthesize proteins/enzymes, metabolism, etc.
 - prepares for duplication if triggered

Interphase

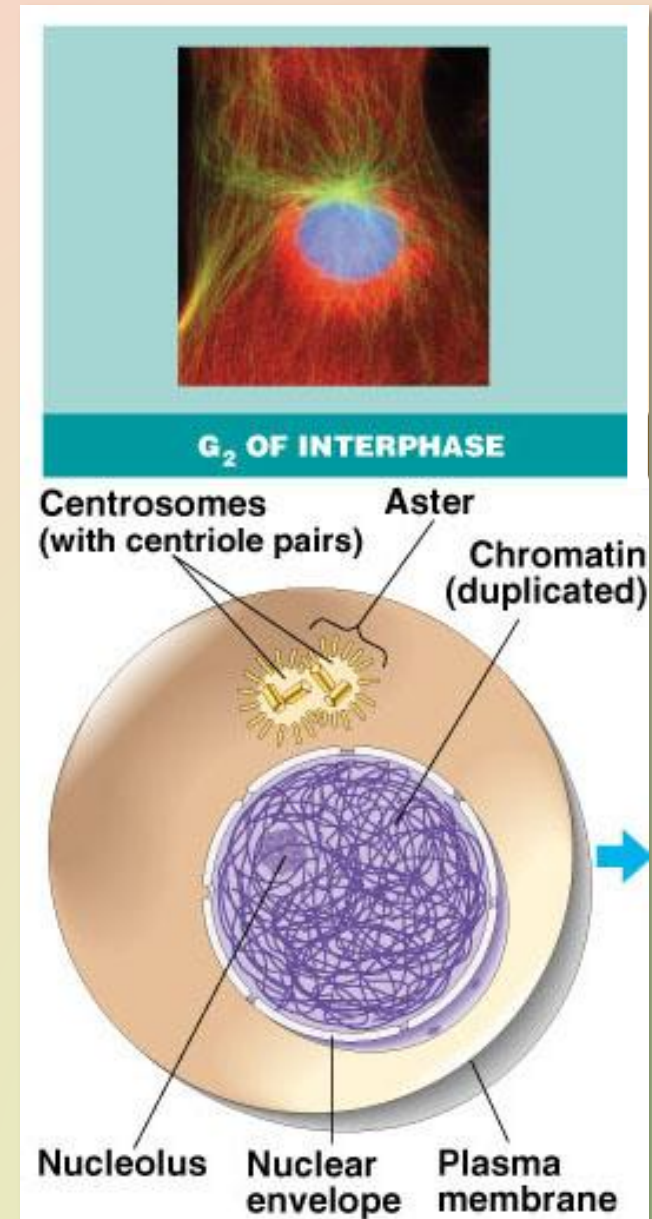

- Divided into 3 phases:
 - $G_1 = 1^{\text{st}}$ Gap (Growth)
 - Non-dividing life
 - $S = \text{DNA } \underline{\text{S}}$ ynthesis
 - copies chromosomes
 - $G_2 = 2^{\text{nd}}$ Gap (Growth)
 - prepares for division
 - cell grows (more)
 - produces organelles, proteins, membranes

signal to
divide

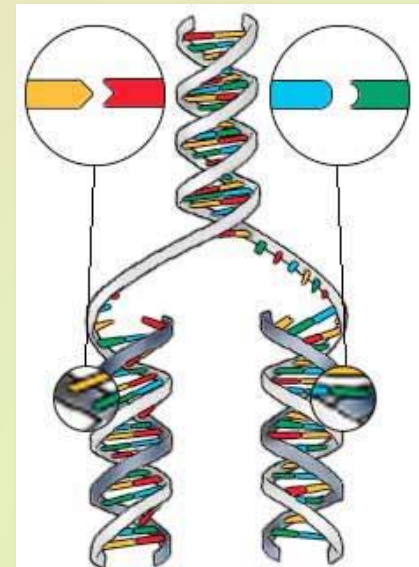

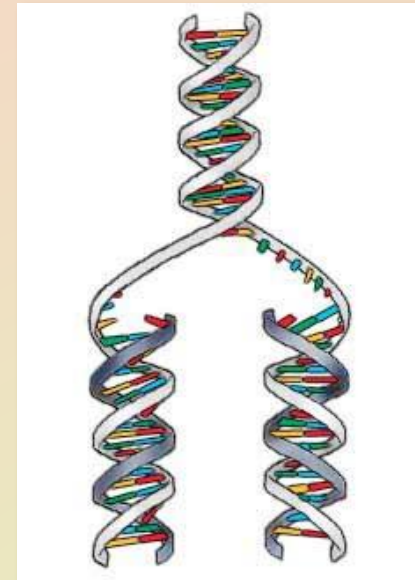

How Interphase Looks

- Nucleus well-defined
 - DNA loosely packed in chromatin fibers

S phase: Copying / Replicating DNA

- Synthesis phase of Interphase
 - dividing cell replicates DNA
 - must separate DNA copies correctly to 2 daughter cells
 - human cell duplicates ~3 meters DNA
 - error rate = ~1 per 100 million bases
 - 3 billion base pairs in mammals
 - ~30 errors per cell cycle
 - » mutations (to somatic (body) cells)

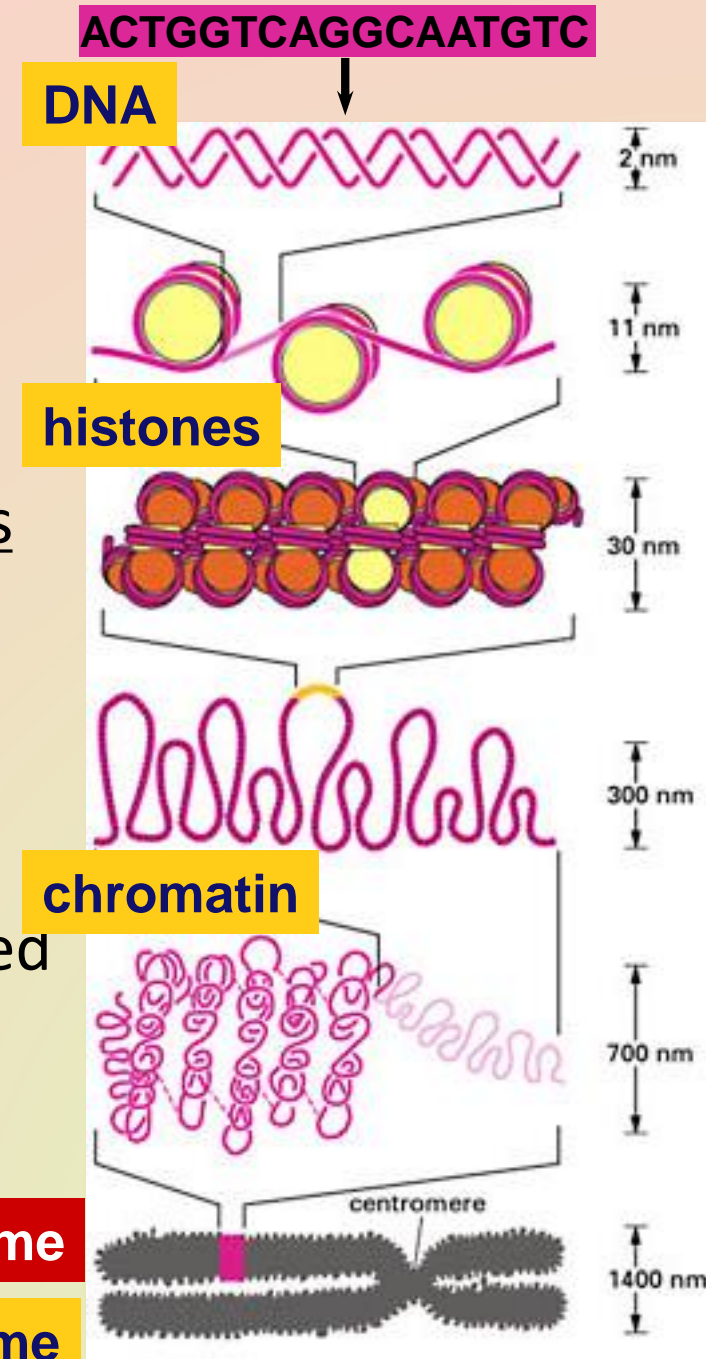

Organizing DNA

- DNA is organized in chromosomes
 - double helix DNA molecule
 - wrapped around histone proteins
 - like thread on spools
 - DNA-protein complex = chromatin
 - organized into long thin fiber
 - Coiled, supercoiled and condensed during mitosis

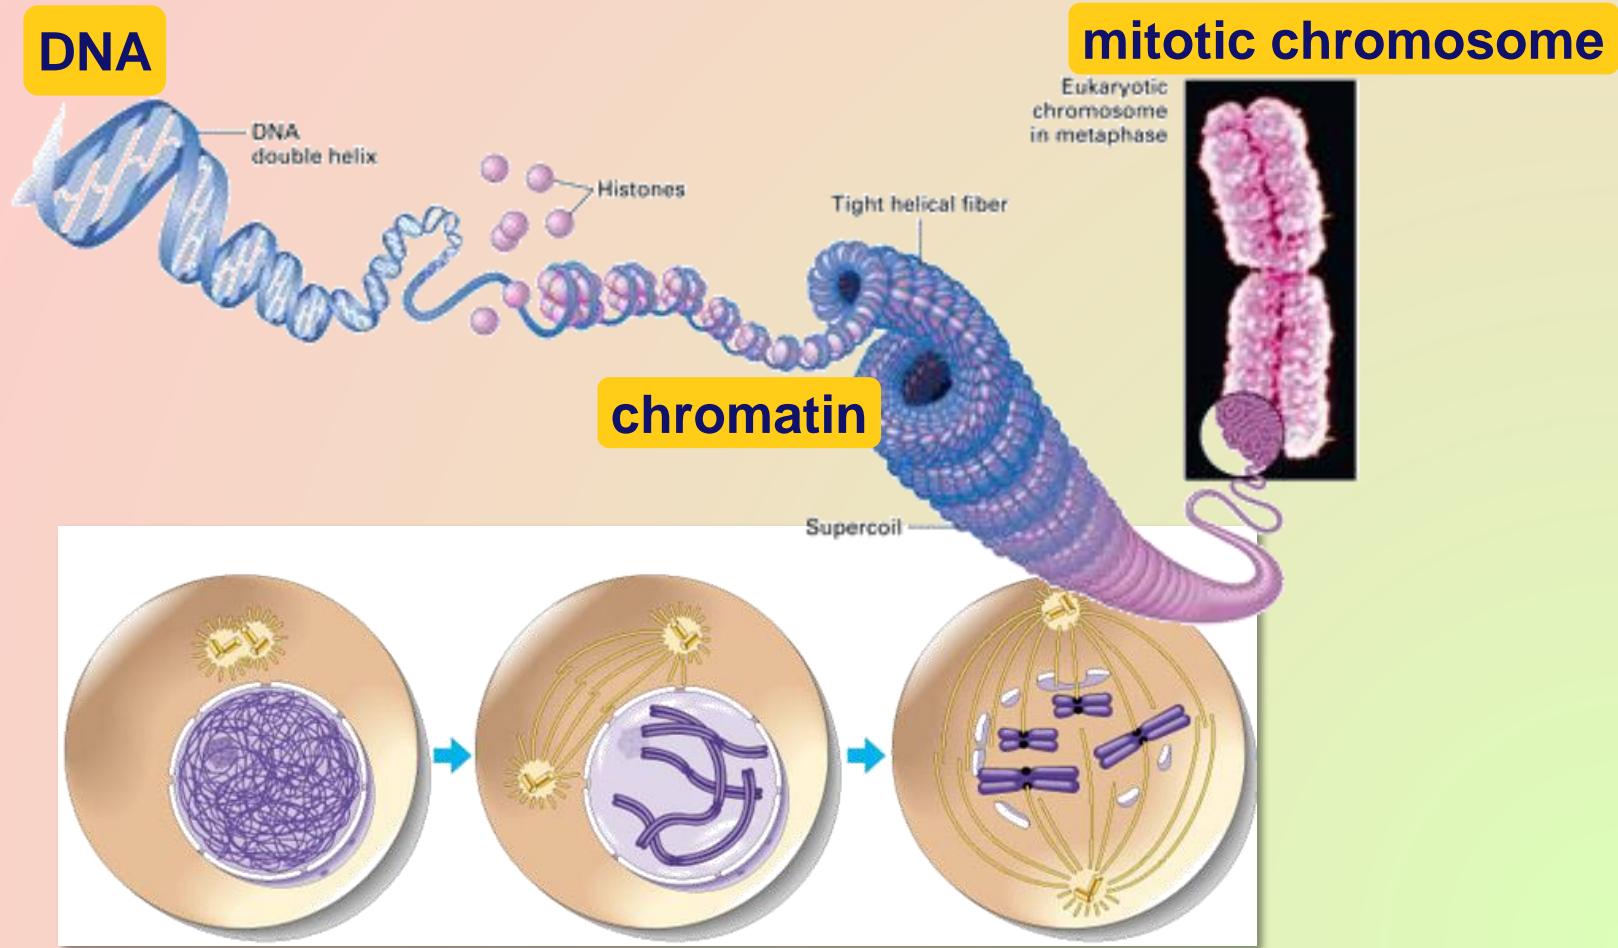

double stranded chromosome

uplicated mitotic chromosome

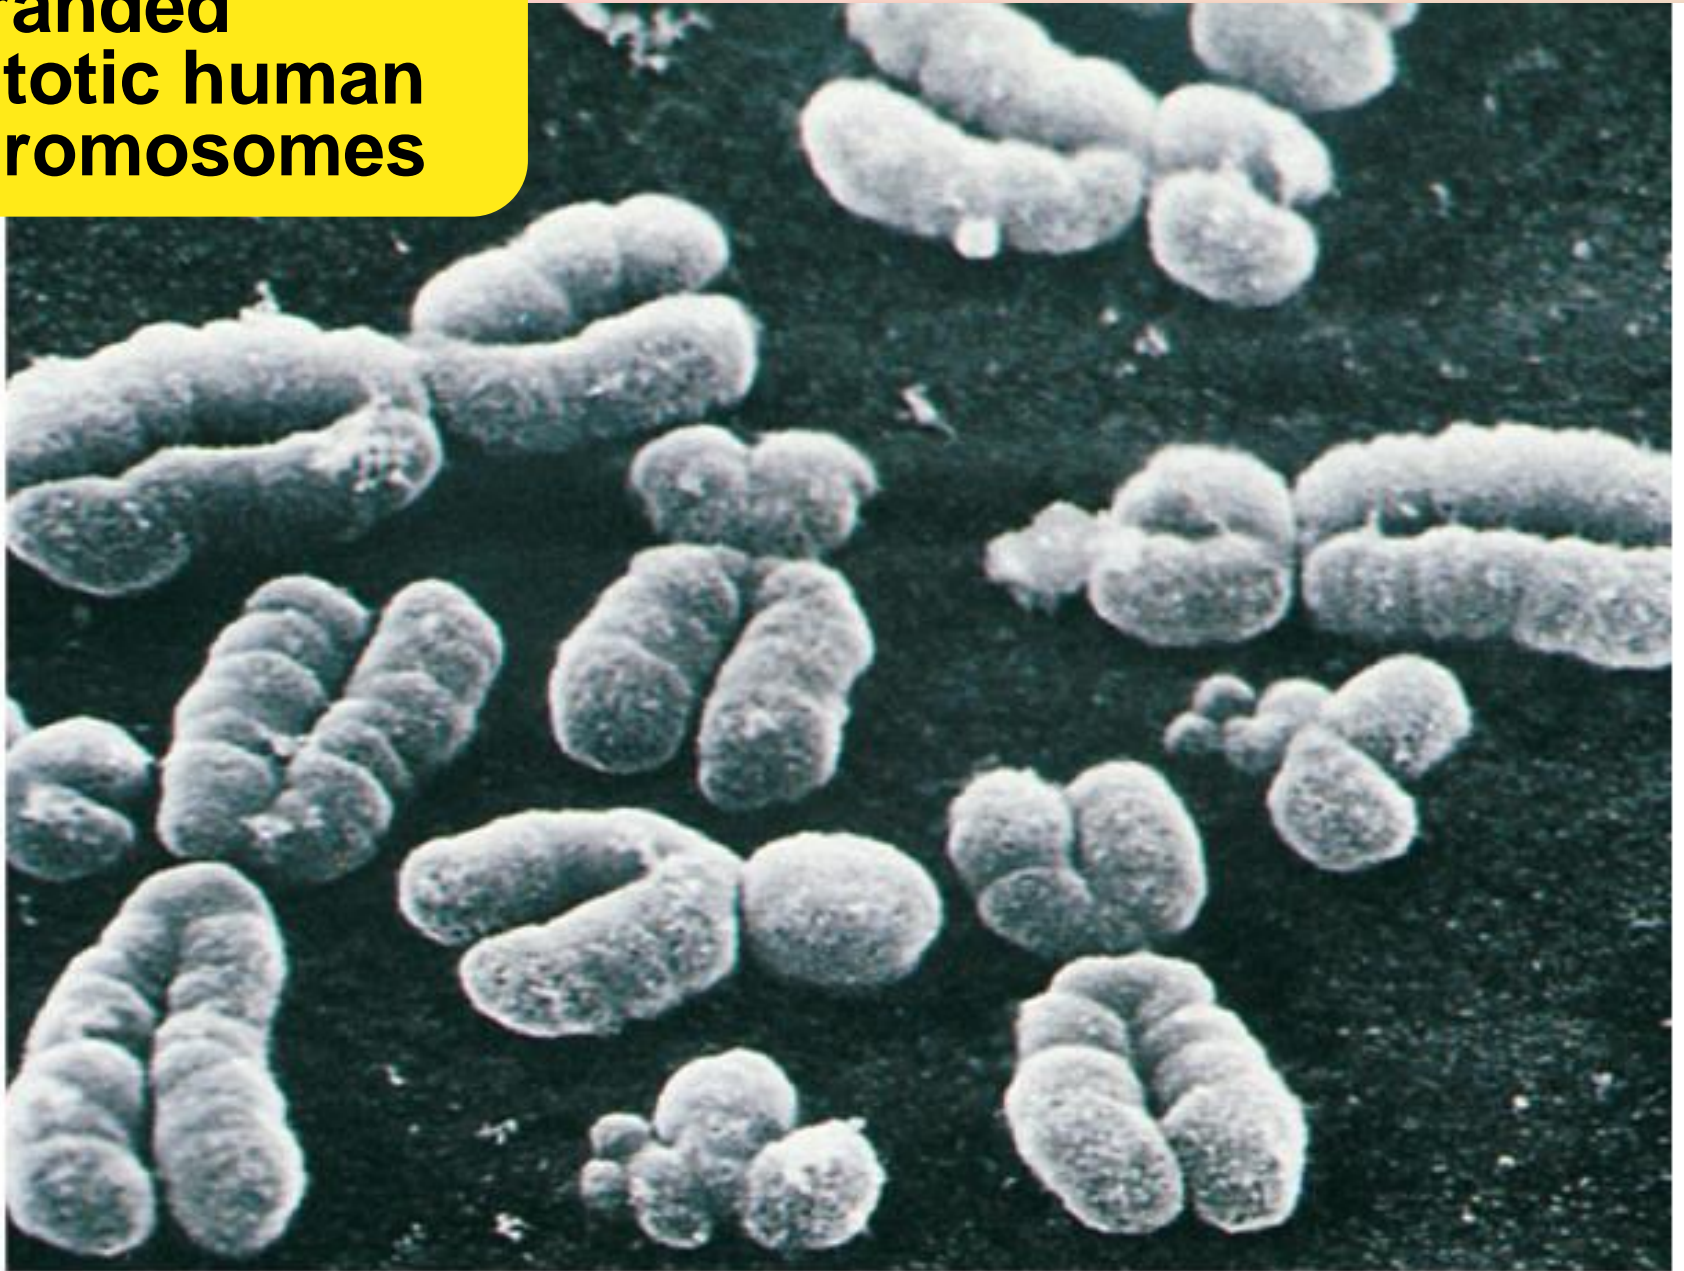

Copying DNA & packaging it...

- After DNA duplication, chromatin condenses
 - coiling & folding to make a smaller package

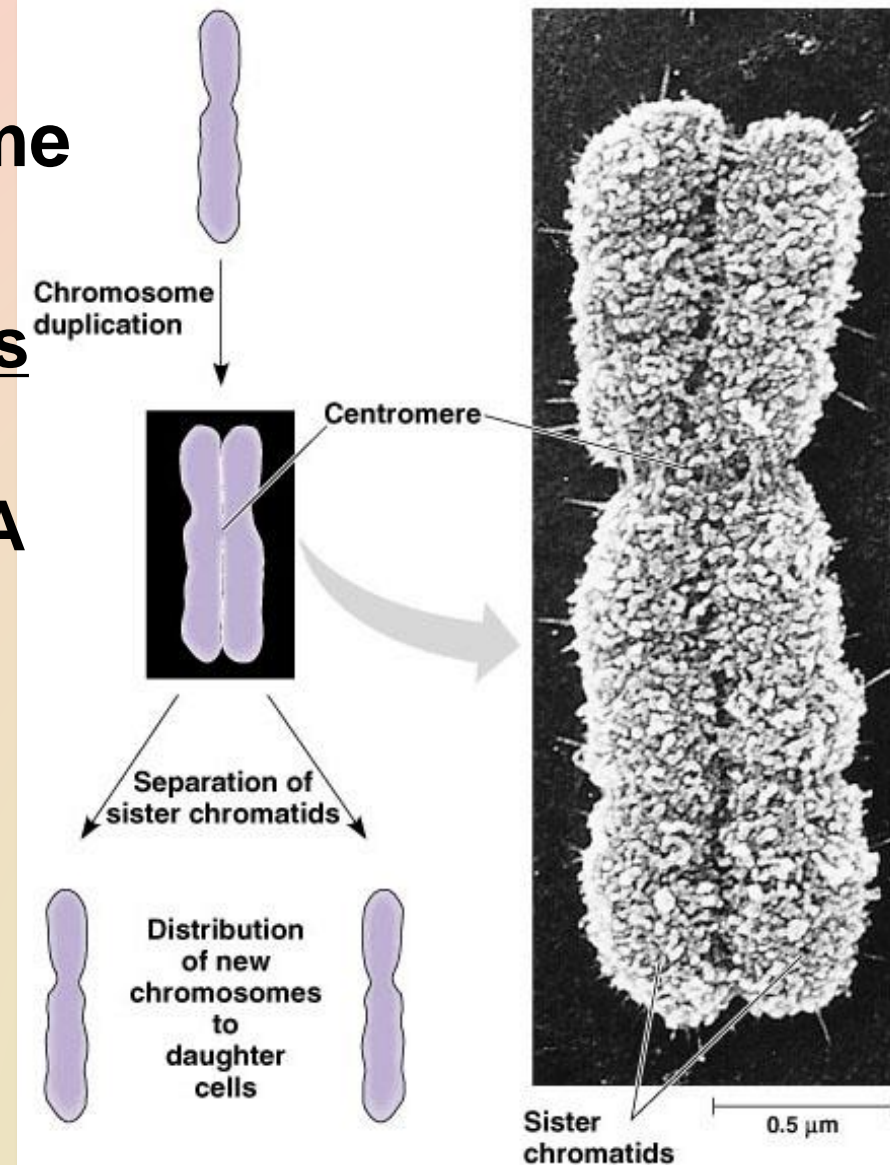

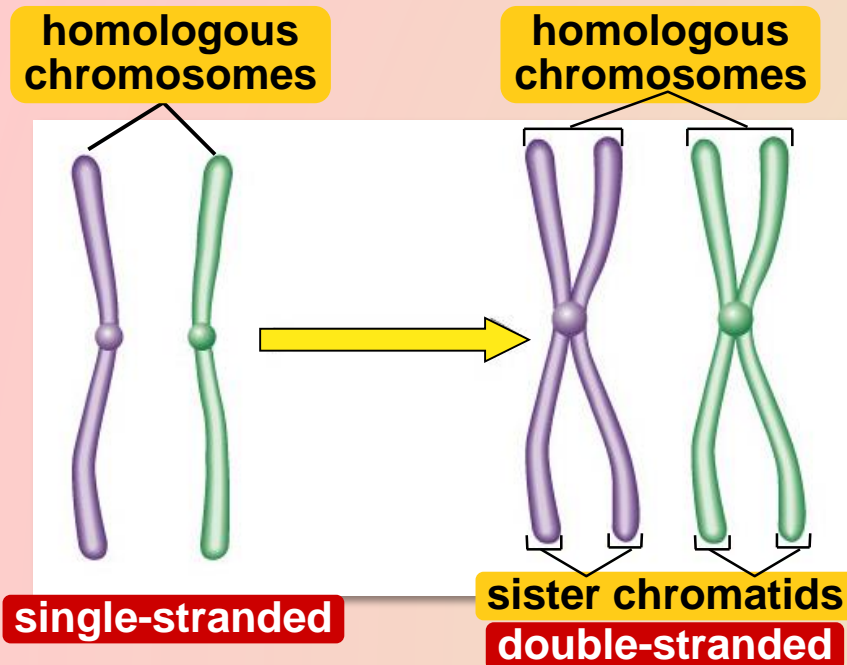

**double-
stranded
mitotic human
chromosomes**

Mitotic Chromosome

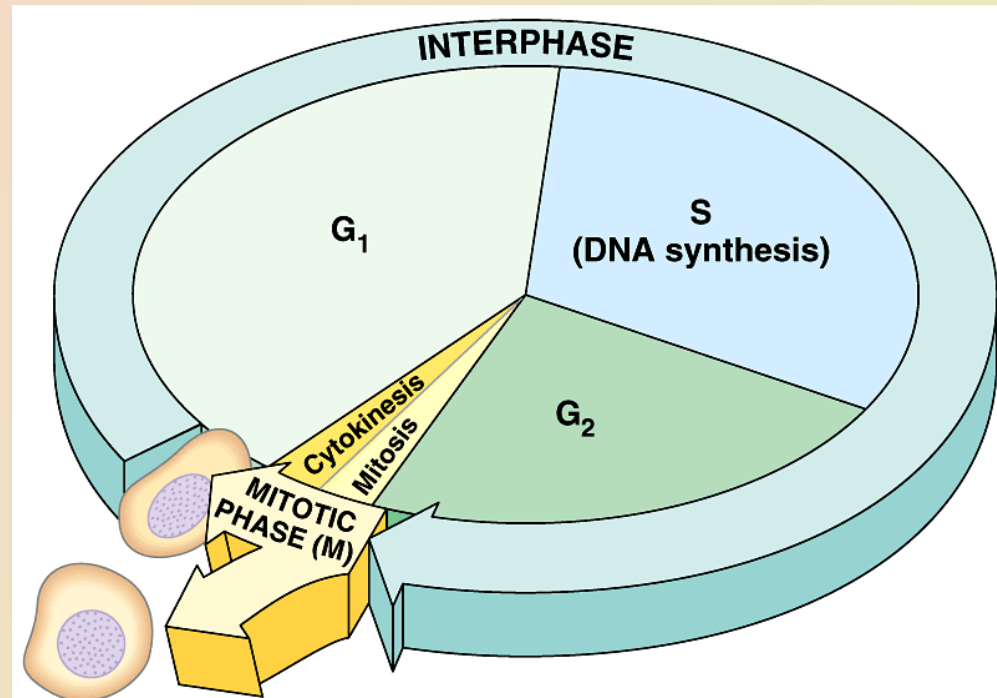

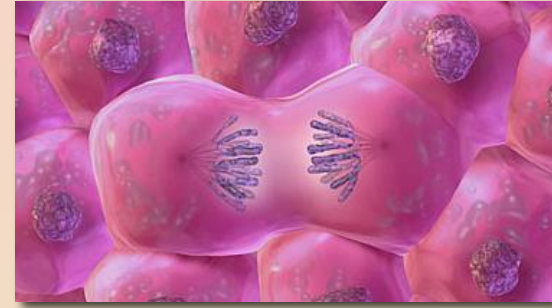

- **Duplicated chromosome**
 - ◆ 2 sister chromatids
 - ◆ narrow at centromeres
 - ◆ contain identical copies of original DNA

homologous = "same information"

Mitosis

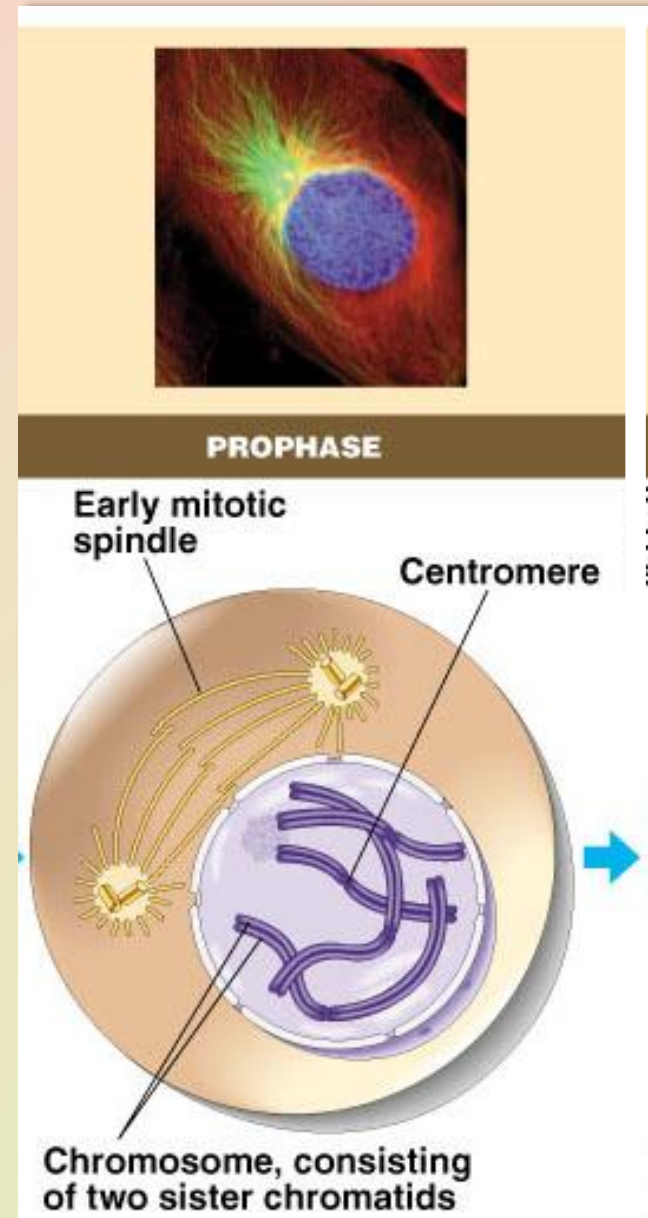

- Dividing cell's DNA between 2 daughter nuclei
- 4 phases
 - prophase
 - metaphase
 - anaphase
 - telophase

Prophase

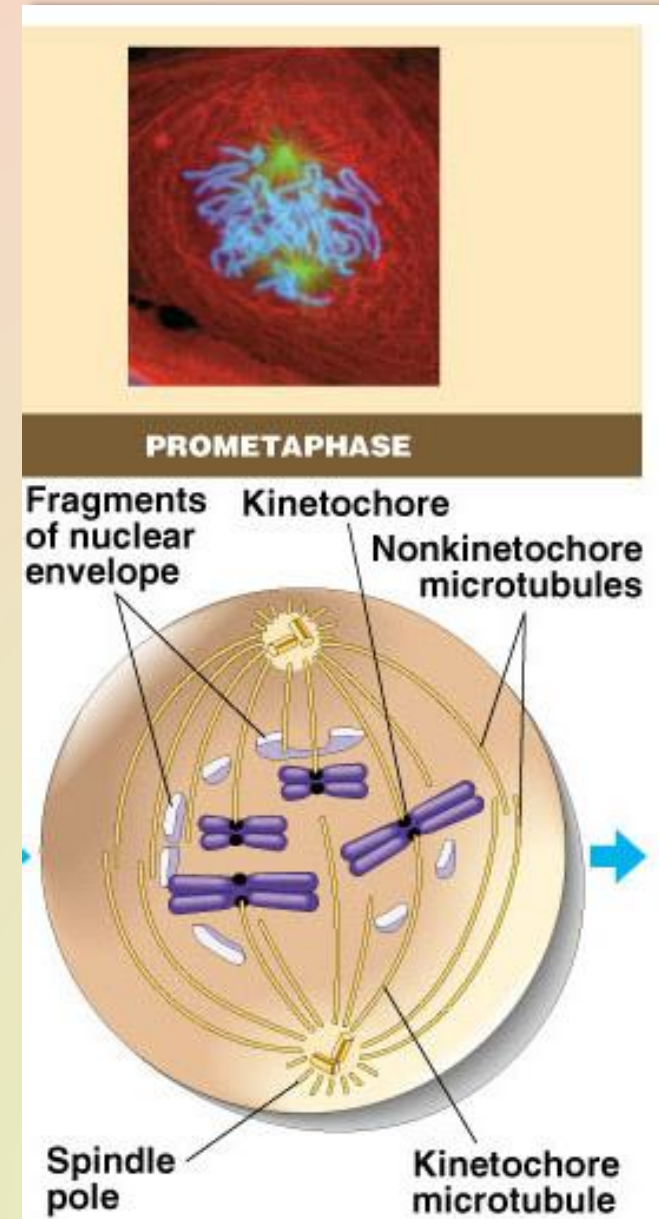

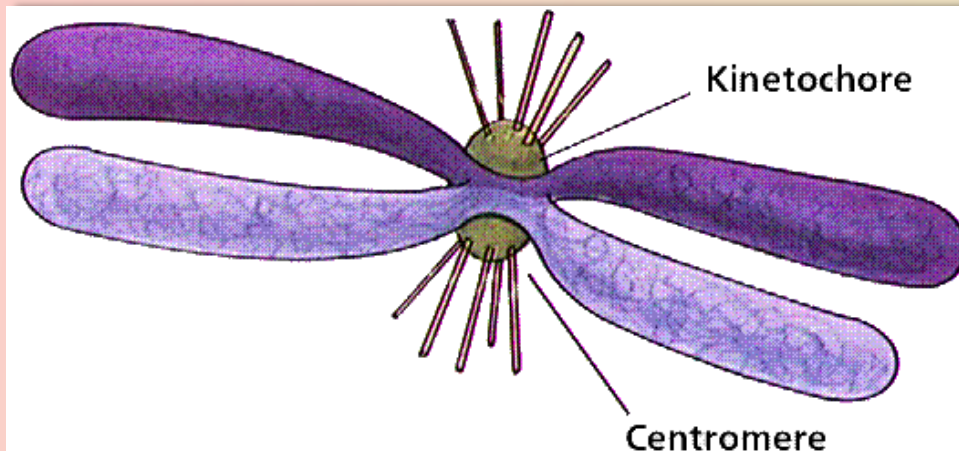

green = key features

- Chromatin condenses
 - visible chromosomes
- Centrioles move to opposite poles of cell in animal cells only
- Microtubules cross cell to form mitotic spindle
- Nucleolus disappears
- Nuclear membrane breaks down

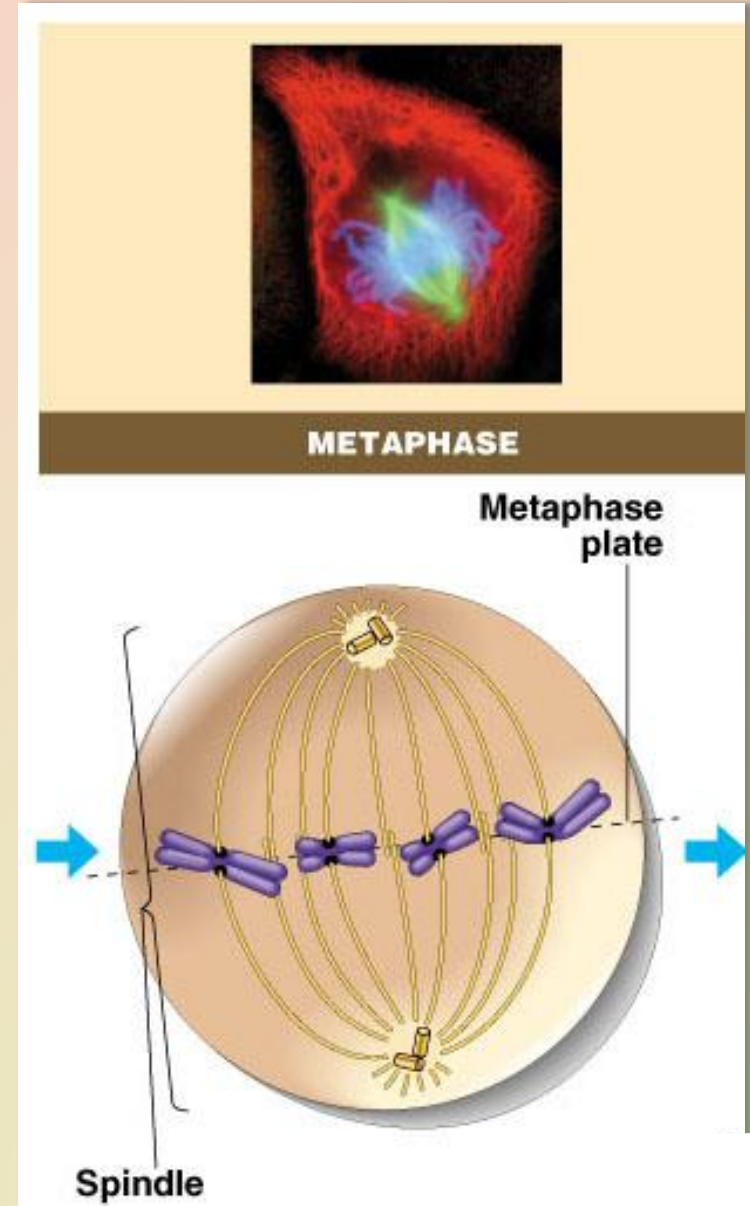

Transition to Metaphase

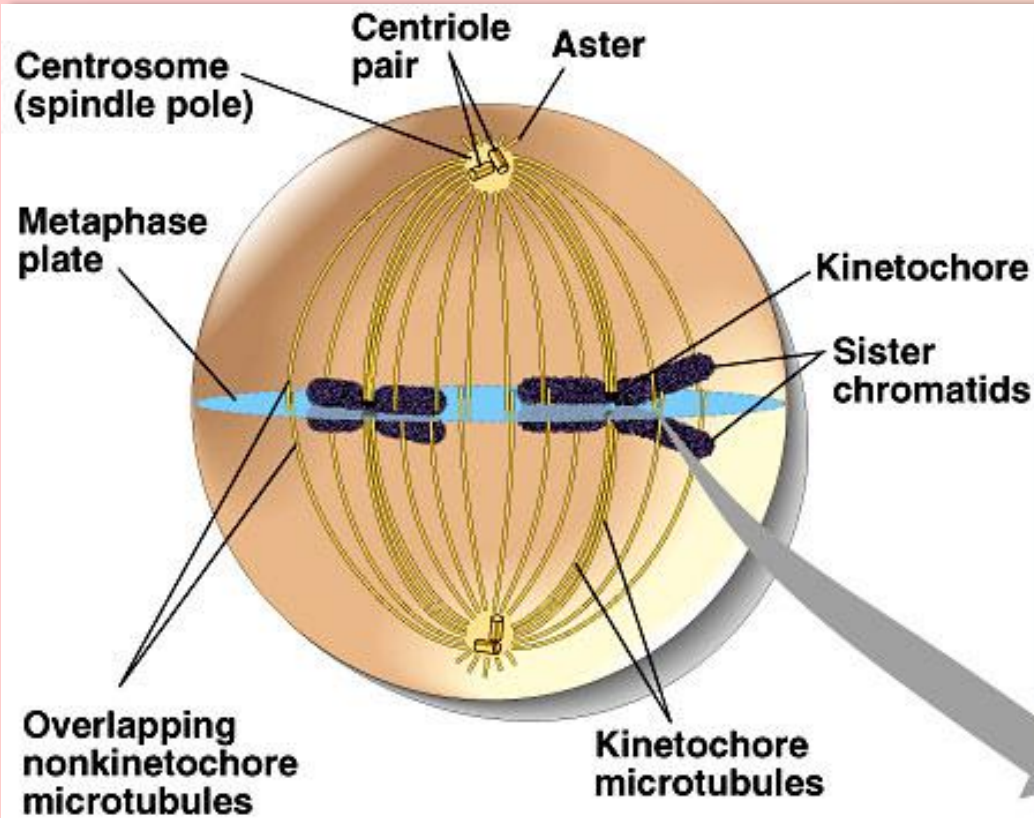

- Prometaphase
 - spindle fibers attach to centromeres
 - Kinetochores connect centromeres to centrioles

Metaphase

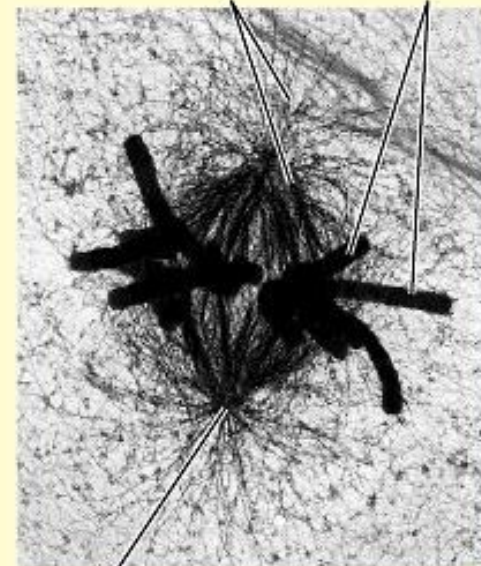

- Chromosomes align along middle of cell
 - metaphase plate
 - meta = middle
 - spindle fibers coordinate movement
 - ensure chromosomes separate properly

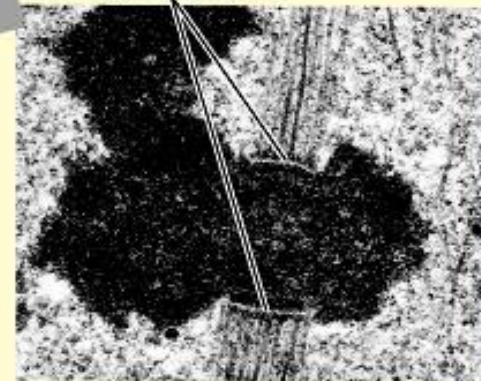

(a) Diagram of two duplicated chromosomes arrayed at the metaphase plate

Microtubules Chromosomes

Centrosome
Kinetochores

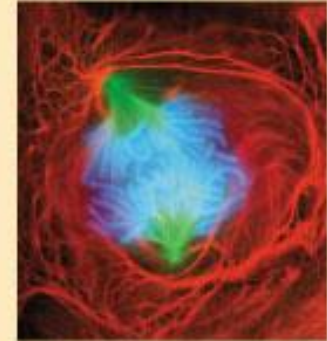

(b) Transmission electron micrographs

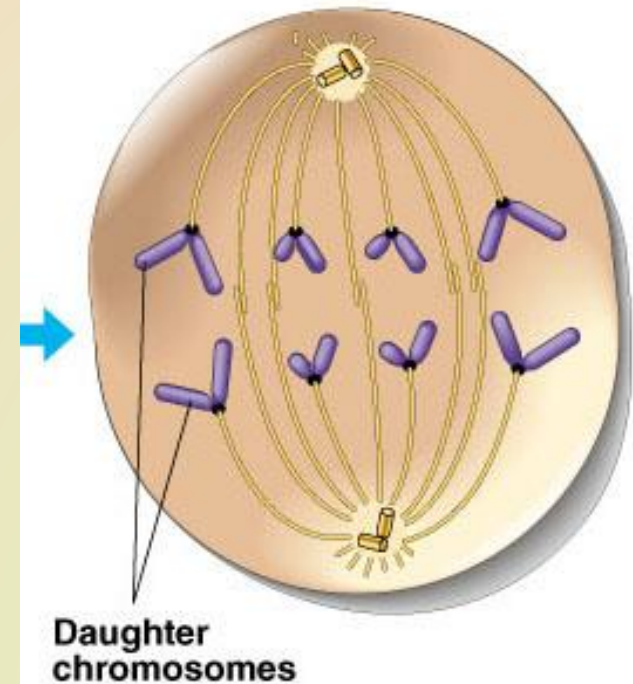

From Dr. Matthew Schibler, *Photoplasma* 137 (1987):29-44.
Reprinted by permission of Springer-Verlag.

Anaphase

- Sister chromatids separate at centromere
 - move to opposite poles
 - pulled by motor proteins
“walking” along microtubules
- Poles move farther apart
 - polar microtubules lengthen

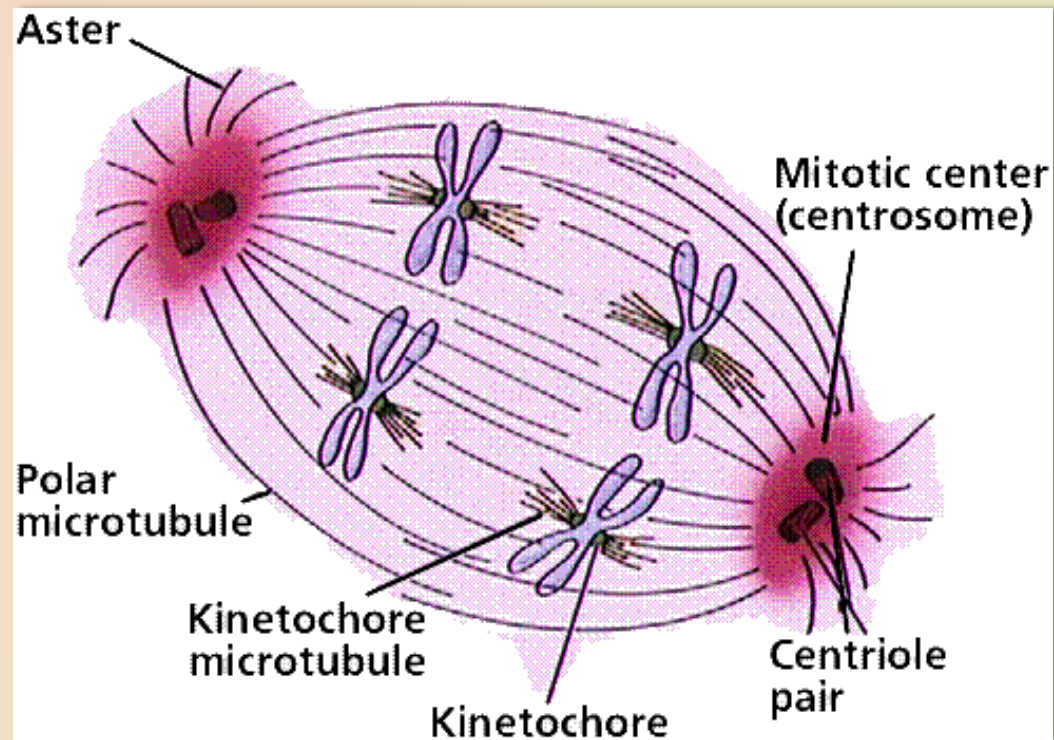

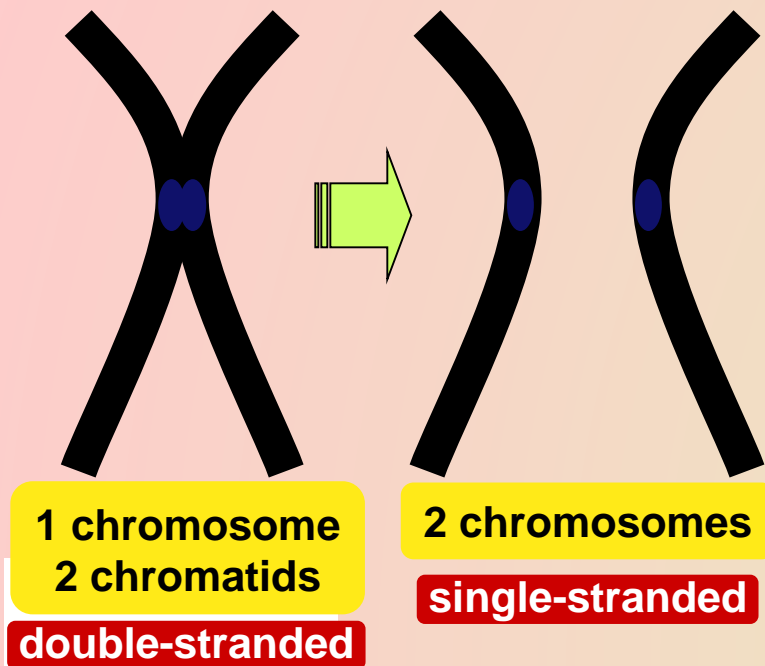

ANAPHASE

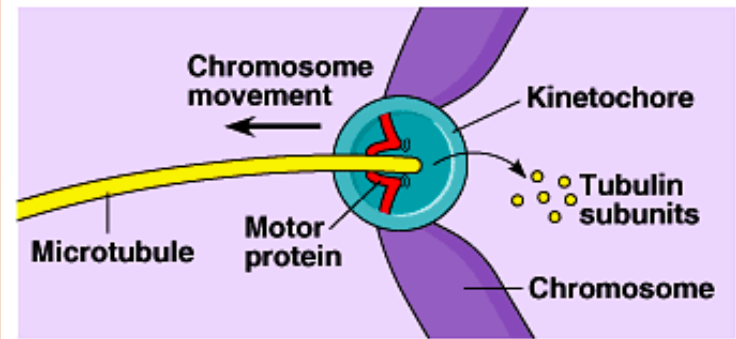

Separation of chromatids

- In anaphase, proteins holding together sister chromatids are inactivated
 - separate to become individual chromosomes

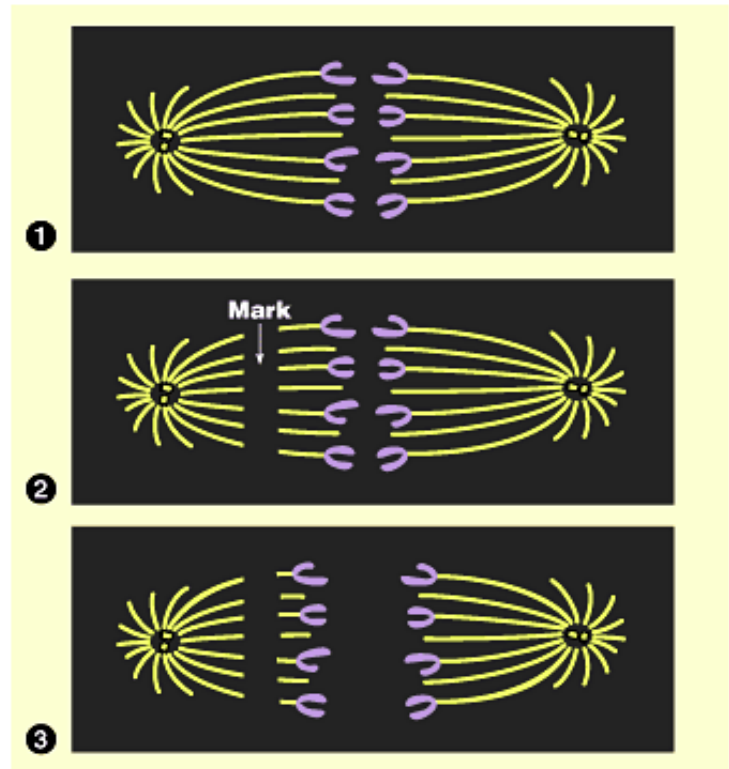

Chromosome movement

- Kinetochore uses motor proteins that “walk” chromosome along attached microtubule
 - microtubule shortens by dismantling at kinetochore (chromosome) end

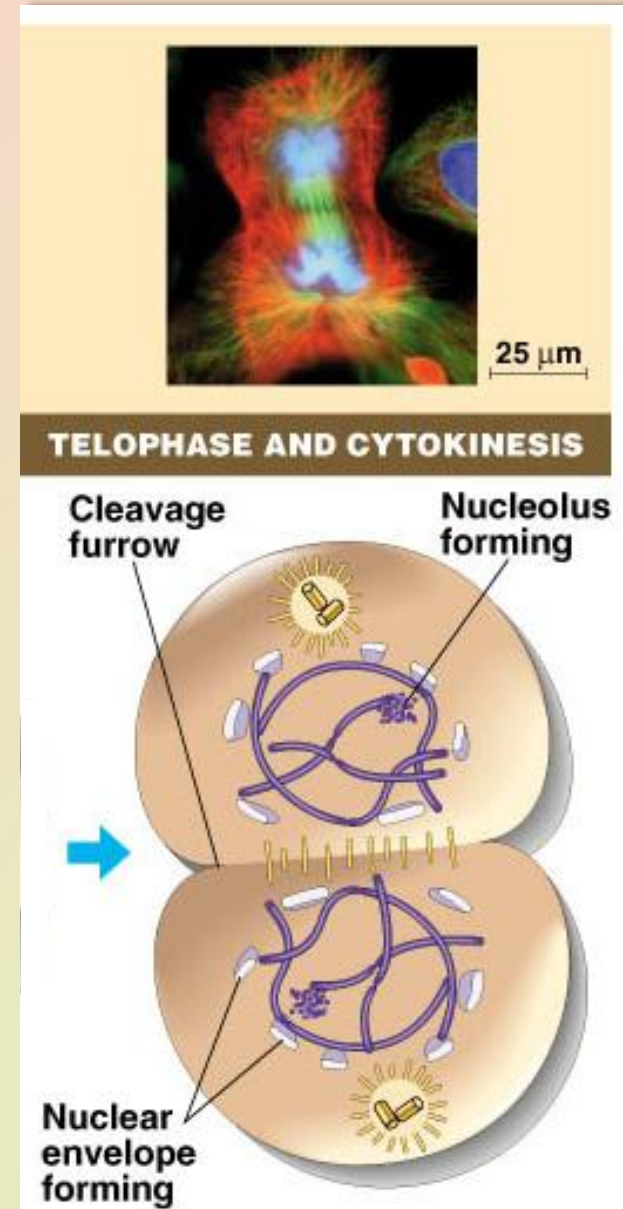

(a) Hypothesis

(b) Experiment

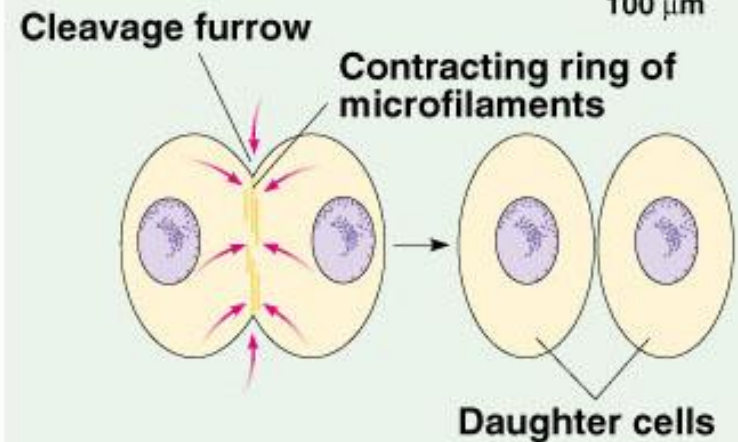

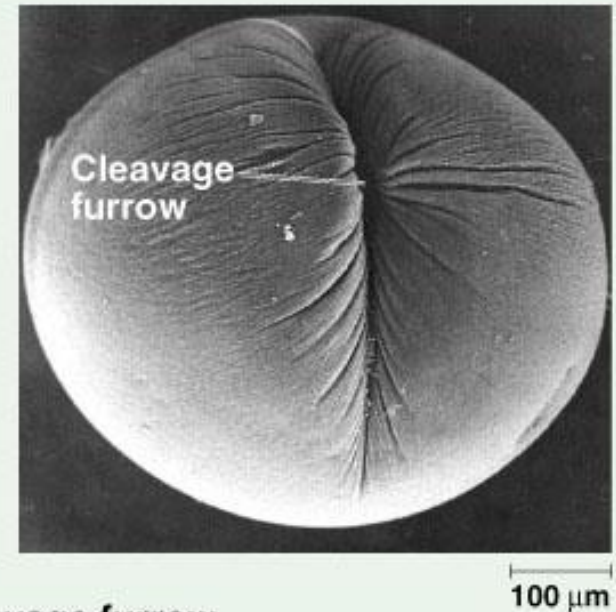

Telophase

- Chromosomes arrive at opposite poles
 - daughter nuclei form
 - chromosomes disperse
- Spindle fibers disperse
- Cytokinesis begins
 - cell division

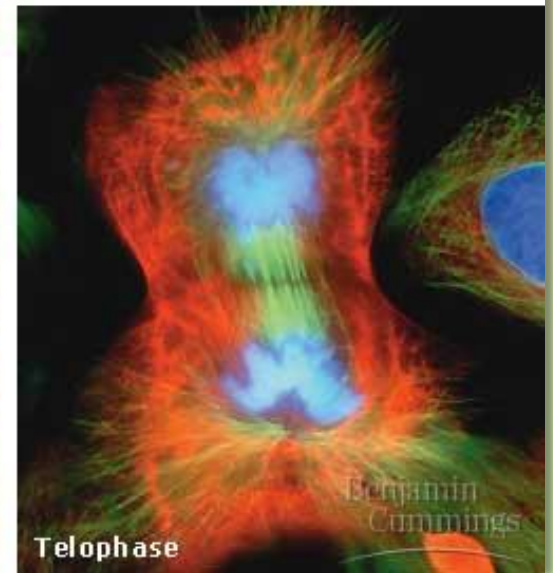

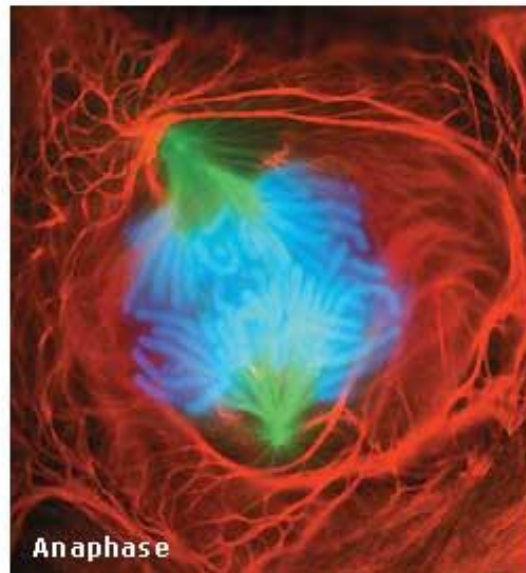

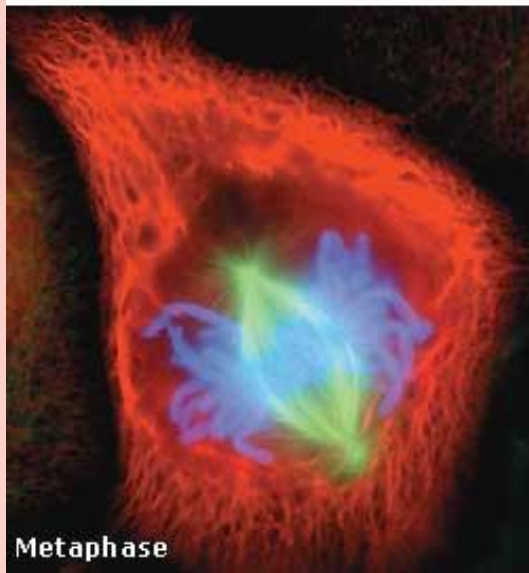

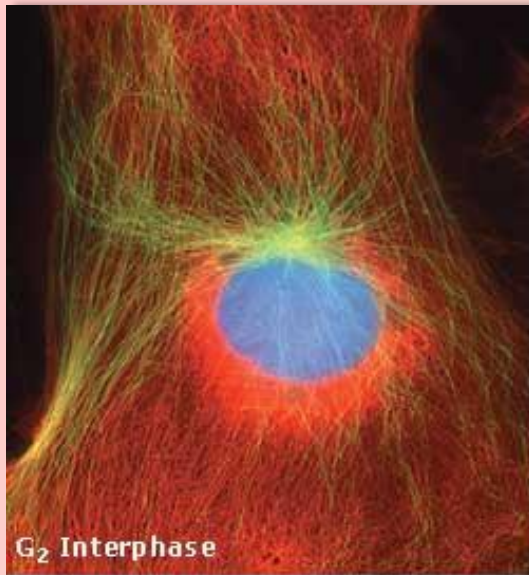

Cytokinesis in Animals

- belt of actin microfilaments around equator of cell
 - Cleavage furrow forms
 - splits cell in two
 - like tightening a draw string

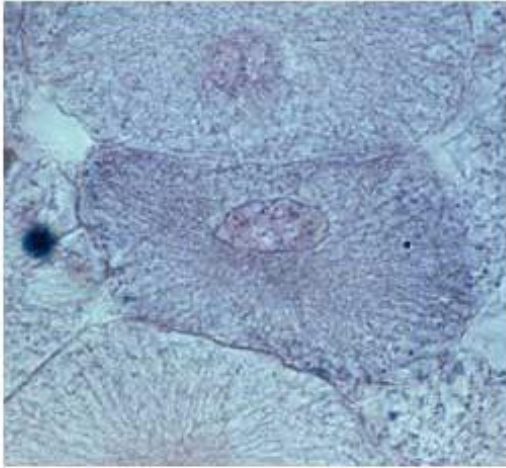

(a) Cleavage of an animal cell

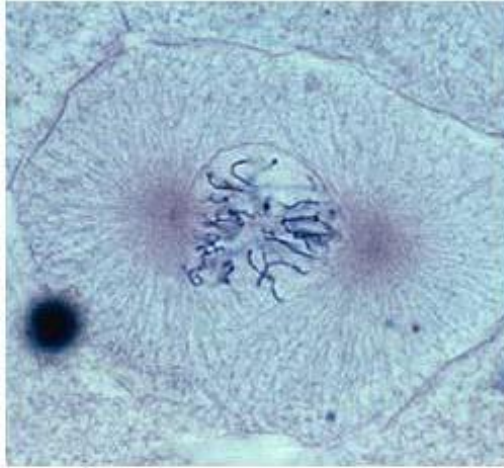

Mitosis in animal cells

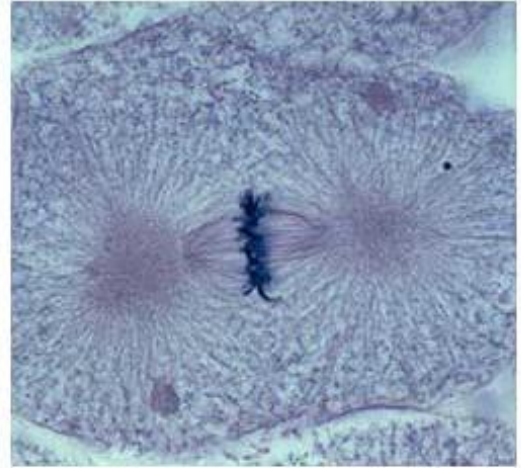

Mitosis in whitefish blastula

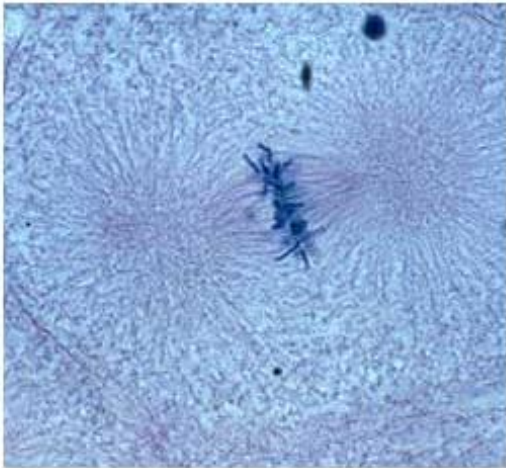

Interphase

Prophase

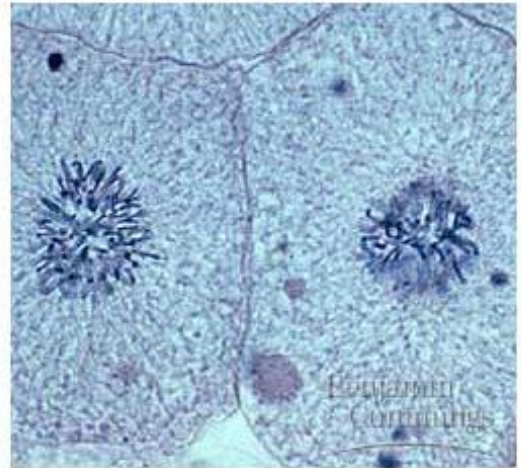

Metaphase

Anaphase

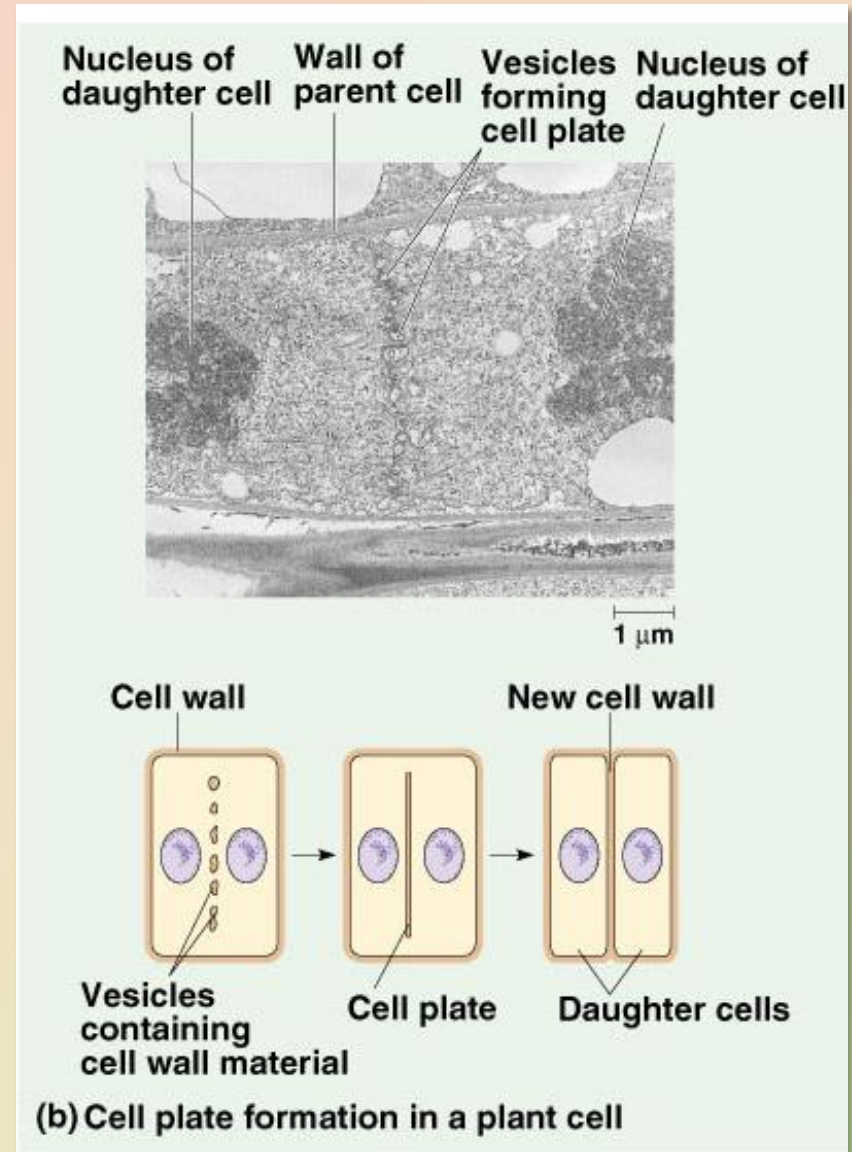

Early Telophase

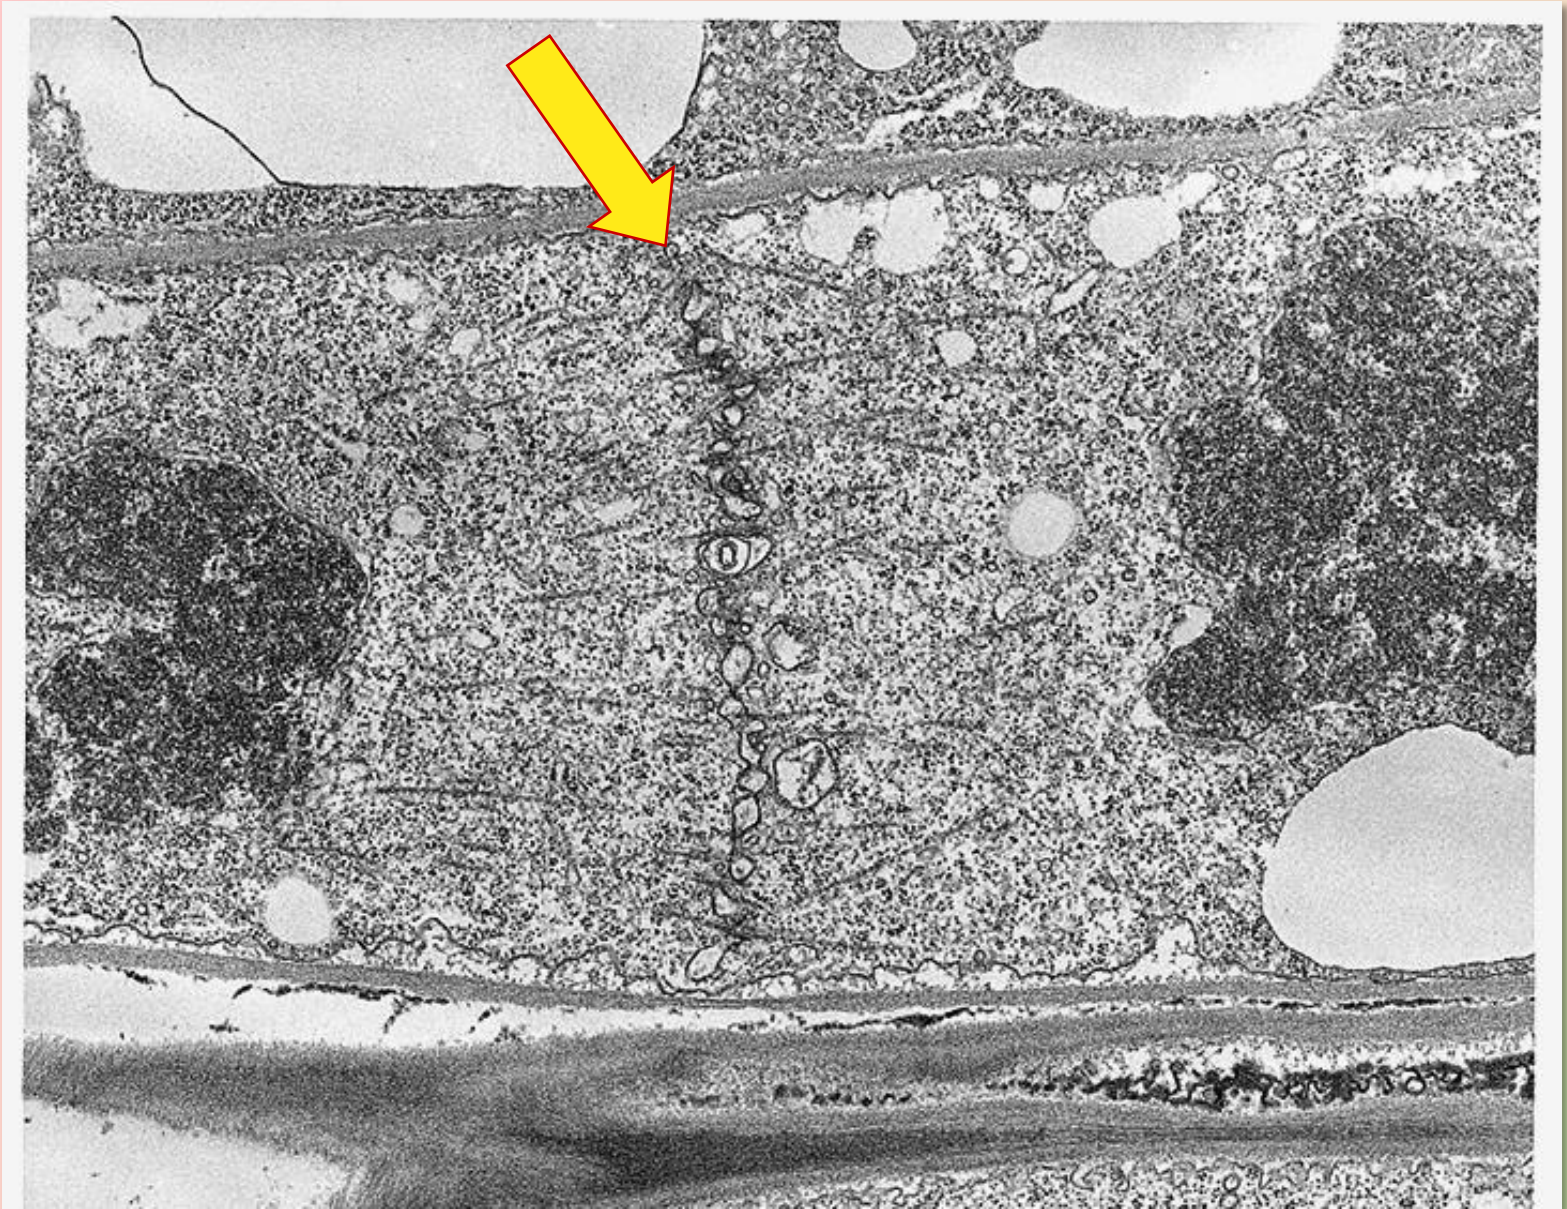

Late Telophase

Cytokinesis in Plants

- cell plate forms
 - Vesicles (from golgi) line up at equator
 - vesicles fuse to form 2 cell membranes
- new cell wall laid down between membranes
 - new cell wall fuses with existing cell wall

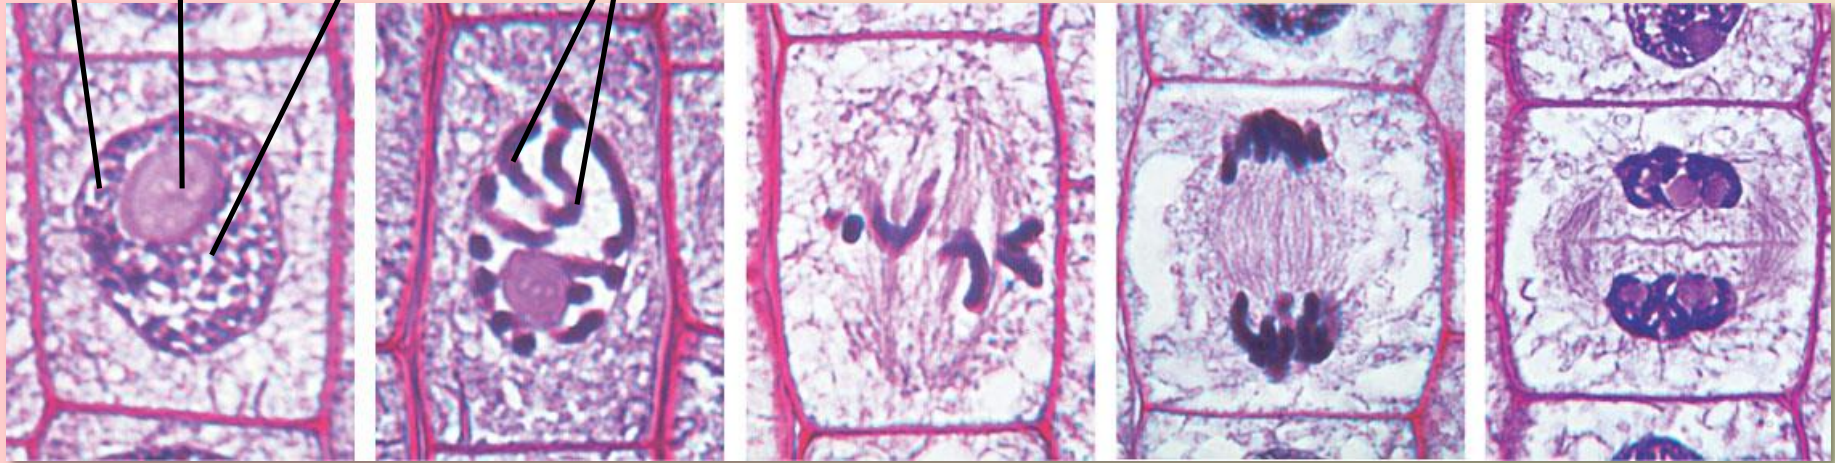

Cytokinesis in plant cell

Mitosis in a plant cell

Nucleus
Nucleolus
Chromatine condensing
Chromosome

1

Prophase.

The chromatin is condensing. The nucleolus is beginning to disappear. Although not yet visible in the micrograph, the mitotic spindle is starting to form.

2

Prometaphase.

We now see discrete chromosomes; each consists of two identical sister chromatids. Later in prometaphase, the nuclear envelope will fragment.

3

Metaphase.

The spindle is complete, and the chromosomes, attached to microtubules at their kinetochores, are all at the metaphase plate.

4

Anaphase.

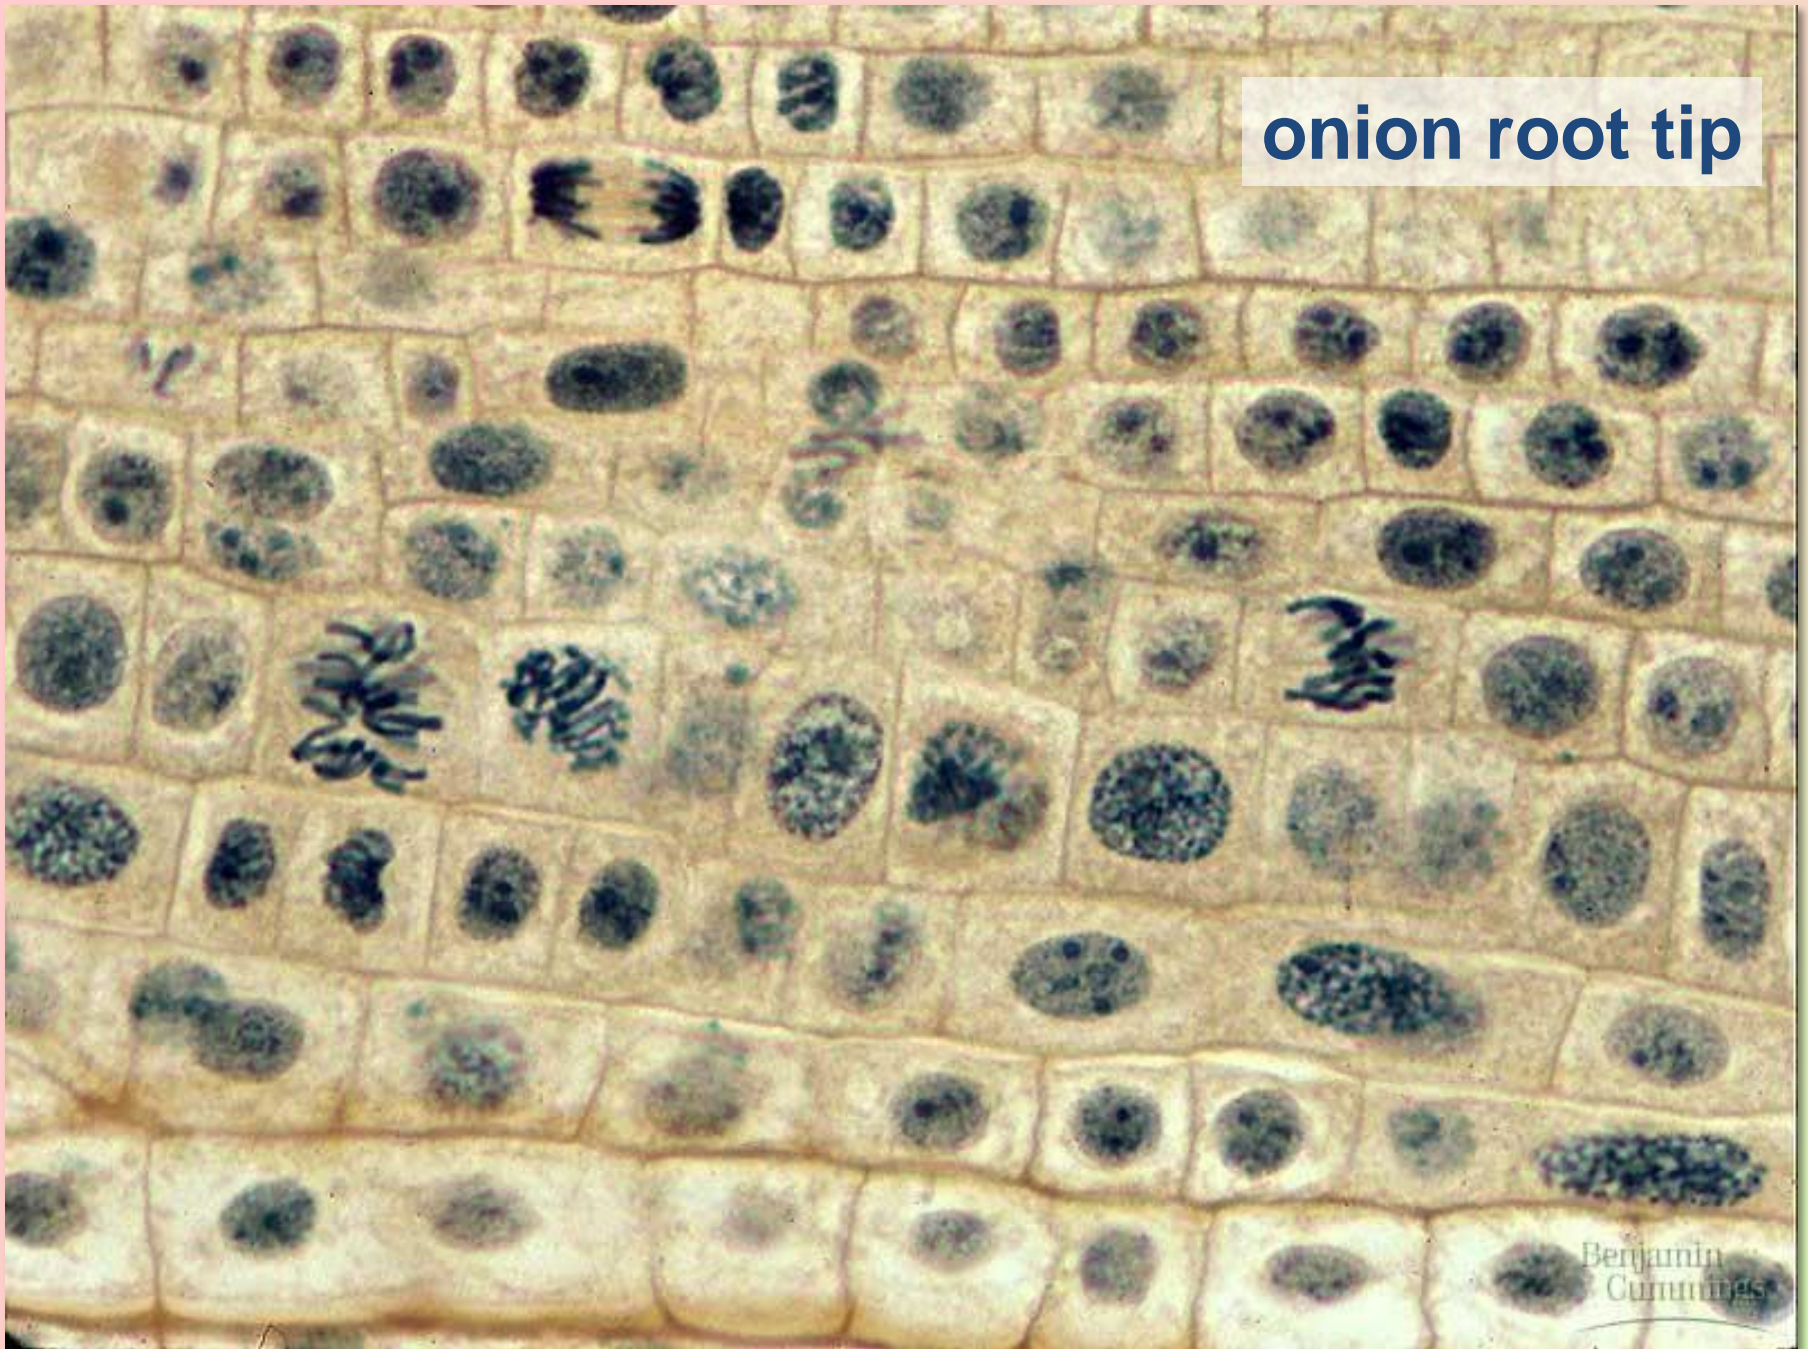

The chromatids of each chromosome have separated, and the daughter chromosomes are moving to the ends of cell as their kinetochore microtubules shorten.

5

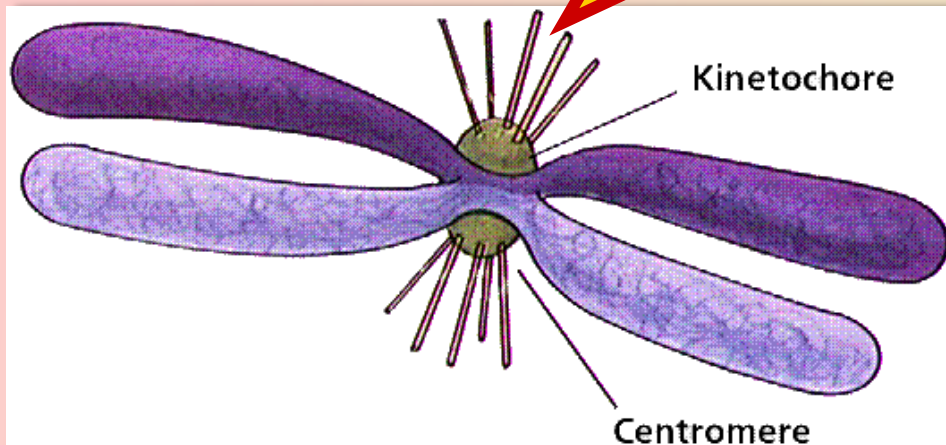

Telophase.

Daughter nuclei are forming. Meanwhile, cytokinesis has started: The cell plate, which will divide the cytoplasm in two, is growing toward the perimeter of the parent cell.

Any Questions??

Review Questions

1. Cytokinesis usually, but not always, follows mitosis. If a cell completed mitosis but not cytokinesis, what would be the result?
 - A. a cell with a single large nucleus
 - B. a cell with high concentrations of actin and myosin
 - C. a cell with two abnormally small nuclei
 - D. a cell with two nuclei
 - E. a cell with two nuclei but with half the amount of DNA

2. Taxol is an anticancer drug extracted from the Pacific yew tree. In animal cells, taxol disrupts microtubule formation by binding to microtubules and accelerating their assembly from the protein precursor, tubulin. Surprisingly, this stops mitosis. Specifically, taxol must affect

- A. the fibers of the mitotic spindle.
- B. anaphase.
- C. formation of the centrioles.
- D. chromatid assembly.
- E. the S phase of the cell cycle.

3. Measurements of the amount of DNA per nucleus were taken on a large number of cells from a growing fungus. The measured DNA levels ranged from 3 to 6 picograms per nucleus. In which stage of the cell cycle was the nucleus with 6 picograms of DNA?

- A. G_0
- B. G_1
- C. S
- D. G_2
- E. M

4. A group of cells is assayed for DNA content immediately following mitosis and is found to have an average of 8 picograms of DNA per nucleus. Those cells would have _____ picograms at the end of the S phase and _____ picograms at the end of G₂.

- A. 8 ... 8
- B. 8 ... 16
- C. 16 ... 8
- D. 16 ... 16
- E. 12 ... 16

5. A particular cell has half as much DNA as some of the other cells in a mitotically active tissue. The cell in question is most likely in

A. G_1 .

B. G_2 .

C. prophase.

D. metaphase.

E. anaphase.
